Smart Location Mapping

This page features interactive mapping tools and data for measuring location efficiency and the built environment.

On this page:

- Background
- Smart Location Database
- Access to Jobs and Workers Via Transit Tool
- National Walkability Index
- Smart Location Calculator
- Suggested Uses

Background

A large body of research has demonstrated that land use and urban form can have a significant effect on transportation outcomes.

- People who live and/or work in compact neighborhoods with a walkable street grid and easy access to public transit, jobs, stores, and services are more likely to have several transportation options to meet their everyday needs.
- As a result, they can choose to drive less, which reduces their emissions of greenhouse gases and other pollutants compared to people who live and work in places that are not location efficient.
- Walking, biking, and taking public transit can also save people money and improve their health by encouraging physical activity.

An EPA-funded meta-analysis of the research, [Travel and the Built Environment](https://www.tandfonline.com/doi/abs/10.1080/01944361003766766) [\[i\]](#), summarized the measurable effects of several built environment variables on residents' travel behavior. These findings can help inform travel demand studies as well as land use and transportation planning studies. However, developing data about these characteristics can be expensive and time consuming.

To respond to this need, EPA developed four data products that consistently measure the built environment and transit accessibility of neighborhoods across metropolitan regions and across the United States. Each product summarizes the characteristics of census block groups [i]. Users can download data, browse the data in interactive maps, or access the data through web services [ii].

- **The Smart Location Database** summarizes more than 90 different indicators associated with the built environment and location efficiency. Indicators include density of development, diversity of land use, street network design, and accessibility to destinations as well as various demographic and employment statistics. Most attributes are available for all U.S. block groups.
- **The Access to Jobs and Workers Via Transit Tool** provides indicators of accessibility to destinations by public transit. Indicators summarize jobs accessible by transit as well as workers, households, and population that can access the block group via transit. Coverage is limited to metropolitan regions served by transit agencies that share their service data.
- **The National Walkability Index** provides walkability scores based on a simple formula that ranks selected indicators from the Smart Location Database that have been demonstrated to affect the propensity of walk trips. Currently, the National Walkability Index dataset ranks each block group relative to all other block groups in the United States, but individuals can use downloadable data and the "how-to" document to construct an index for a smaller universe of block groups, like a state, metropolitan area, or city.
- **The Smart Location Calculator** is a dataset and interactive tool that measures the location efficiency of workplace locations. Developed by EPA and the General Services Administration (GSA), the interactive map allows users to explore the data, download the dataset, and access the accompanying documentation.

Smart Location Database

The Smart Location Database is a nationwide geographic data resource for measuring location efficiency. It includes more than 90 attributes summarizing characteristics, such as housing density, diversity of land use, neighborhood design, destination accessibility, transit service, employment and demographics. Most attributes are available for every census block group in the United States.

EPA first released a beta version of the Smart Location Database in 2011. The initial full version was released in 2013, and the database was updated to its current version in 2021.

Access the Data

- Interactive map viewer [↗](#)
- Download data for all areas with coverage

- Metadata
- Web services <<https://geodata.epa.gov/arcgis/rest/services/oa/smartlocationdatabase/mapserver>>
- Smart Location Database Technical Documentation and User Guide
<https://epa.gov/system/files/documents/2023-10/epa_sld_3.0_technicaldocumentationuserguide_may2021_0.pdf> has a full description of all available variables, data sources, data currency, data coverage and known limitations.

Figure 1: Transit service density in the Los Angeles metropolitan region. The map shows patterns of spatial variation in transit service availability and density in Los Angeles and its surrounding cities and suburbs.

Sample Variables Included in the Smart Location Database

Category	Variables
Density	Gross residential density (housing units per acre) on unprotected land Gross population density (people per acre) on unprotected land Gross employment density (jobs per acre) on unprotected land
Diversity of land use	Jobs per housing unit Employment entropy (a measure of employment diversity) Employment and housing entropy

Category	Variables
Urban design	Street intersections per square mile High-speed road network density
Transit service*	Aggregate transit service frequency, afternoon peak period Transit service density, afternoon peak period Distance to nearest transit stop
Destination accessibility by transit*	Jobs within a 45-minute transit commute Working-age population within a 45-minute transit commute
Destination accessibility by car	Jobs within a 45-minute drive Working-age population within a 45-minute drive
Demographics	Percentage of households with no car, 1 car, or 2 or more cars Percentage of workers that are low, medium, or high wage (by home and work locations)
Employment	Employment totals broken down by 5-tier classification scheme Employment totals broken down by 8-tier classification scheme

*Only available in areas served by transit agencies that share transit data in GTFS format [🔗 <https://developers.google.com/transit/gtfs/>](https://developers.google.com/transit/gtfs/).

Access to Jobs and Workers Via Transit Tool

The Access to Jobs and Workers Via Transit tool is a free geospatial data resource and web mapping tool for comparing the accessibility of neighborhoods via public transit service. Its indicators summarize accessibility to jobs as well as accessibility by workers, households, and population.

Coverage is limited to metropolitan regions served by transit agencies that share their service data in a standard format called GTFS [↗](https://developers.google.com/transit/gtfs/) <<https://developers.google.com/transit/gtfs/>> .

- Access to Jobs and Workers Via Transit - Technical Documentation and User Guide <https://epa.gov/sites/default/files/2014-03/documents/sld_trans45_ug_0.pdf> has a full description of data sources, data coverage (full list of metropolitan areas covered by GTFS) and other known limitations.

Figure 2: This map shows the percentage of all jobs in the Washington, D.C. metropolitan region that are accessible by transit.

Sample Variables Included in This Dataset

Map Layer Name	Description
Accessibility Index	An index of the relative accessibility of a block group compared to other block groups in the same metropolitan region, as measured by travel time to working-age population via transit. Values closer to 1 are more accessible.
Population with access by transit	Total population able to access the block group within a 45-minute transit and walking commute.
Percentage of population with access by transit	Total population able to access the block group within a 45-minute transit and walking commute as a percentage of total regional population.

Map Layer Name	Description
Jobs accessible by transit	Total jobs reachable within a 45-minute transit and walking commute.
Percentage of regional jobs accessible by transit	Total jobs reachable within a 45-minute transit and walking commute as a percentage of total regional jobs.
Workers with access by transit	Employed population able to access the block group within a 45-minute transit commute from their home location.
Percentage of workers with access by transit	Employed population able to access the block group within a 45-minute transit commute from their home location as a percentage of total regional employed population.
Low-wage workers with access by transit	Workers earning \$1,250 or less per month that can reach the block group within a 45-minute transit commute from their home location.
Percentage of all low-wage workers in region with access by transit	Low-wage workers that can reach the block group within a 45-minute transit commute from their home location as a percentage of all low-wage workers in region.
Low-medium wage workers with access by transit	Workers earning \$3,333 or less per month that can reach the block group within a 45-minute transit commute from their home location.
Percentage of all low-medium wage workers in region with access by transit	Low-medium wage workers that can reach the block group within a 45-minute transit commute from their home location as a percentage of all low-medium wage workers in region.

National Walkability Index

The National Walkability Index is a nationwide geographic data resource that ranks block groups according to their relative walkability. The national dataset includes walkability scores for all block groups as well as the underlying attributes that are used to rank the block groups.

- National Walkability Index User Guide and Methodology
<<https://epa.gov/smartgrowth/national-walkability-index-user-guide-and-methodology>> describes how to use the index and the methodology used to derive the index and ranked scores for its inputs.

Figure 3: This map shows the National Walkability Index results for block group scores in the Chicago metropolitan area and some midwestern states.

Sample Variables Included in This Dataset

Dataset Field Name	Description
NatWalkInd	National Walkability Index score. Calculated by weighted formula using results of indicator rank scores.
D2A_EPHHM	The mix of employment types and occupied housing. A block group with a diverse set of employment types (such as office, retail, and service) plus a large quantity of occupied housing units will have a relatively high value. Higher values correlate with more walk trips.
D2B_E8MIXA	The mix of employment types in a block group (such as retail, office, or industrial). Higher values correlate with more walk trips.
D3b	Street intersection density (pedestrian-oriented intersections). Higher intersection density is correlated with more walk trips.
D4a	Predicted commute mode split - proportion of workers in the block group who carpool.
D2A_Ranked	Resulting rank of block group for D2A_EPHHM within all block groups. Range from 1-20, higher ranks indicate more walk trip likelihood.
D2B_Ranked	Resulting rank of block group for D2B_E8MIXA within all block groups. Range from 1-20, higher ranks indicate more walk trip likelihood.
D3B_Ranked	Resulting rank of block group for D3B within all block groups. Range from 1-20, higher ranks indicate more walk trip likelihood.

Dataset Field Name	Description
D4A_Ranked	Resulting rank of block group for D4A within all block groups. Range from 1-20, higher ranks indicate more walk trip likelihood.

Smart Location Calculator

The Smart Location Calculator [🔗 <https://www.slc.gsa.gov/slc/>](https://www.slc.gsa.gov/slc/) is a simple tool for exploring how workplace location affects worker commute travel. The tool provides location efficiency scores for a user-entered address, as well as location efficiency data summarized at the block group level. All of the scores are relative to the region. Other indicators include worker commute greenhouse gas emissions, mode share, vehicle miles traveled, and workplace accessibility via transit.

Only the Smart Location Index scores and related variables from the 2021 Smart Location Database version are available at this time. This page will be updated when data for other metrics, including transit accessibility and mode split, are available.

Access the Data

- Interactive Map Viewer [🔗 <https://www.slc.gsa.gov/slc/>](https://www.slc.gsa.gov/slc/)

Figure 4: This shows Smart Location Index block group scores mapped in the Columbus, Ohio, metropolitan area.

Sample Variables Included in This Dataset

Dataset Field Name	Description
Score	Smart Location Index (SLI). Ranges in value from 0-100, where 0 indicates the least location-efficient site in the region, and 100 indicates the most location-efficient site. These scores are relative to the region and should not be compared across regions.
GHG	Commute greenhouse gas emissions per worker per year in pounds
GHG_av	Average GHG for the region (CBSA or county)

Suggested Uses

- **Assessing and comparing neighborhood conditions**

Users can browse either dataset using a simple interactive map to assess and compare conditions across different neighborhoods in their communities. The Access to Jobs and Workers Via Transit tool includes regional benchmarks to compare the level of transit access of a neighborhood to the highest and average level of access for neighborhoods in the same metropolitan region.

- **Evaluating and prioritizing investments in location-efficient areas**

Much like energy efficiency, location efficiency reduces resource demands while fostering a healthier, more sustainable built environment and providing equitable access to jobs and services. Location-efficient facilities or public-sector infrastructure investments are generally accessible via multiple transportation options, including:

- Public transit and active transportation.
- Centrally located in a region providing greater access and reduced travel distances.
- Integrated within a mixed-use environment that offers easy access to services and destinations.

- **Scenario planning and travel demand modeling**

Planners can use indicators from these datasets as baseline information for scenario planning, sketch planning, and travel demand studies when more detailed or consistent local data are unavailable. Analysts can also use elasticities found in the research literature to adjust outputs of travel or activity models that are otherwise insensitive to variation in the built environment.

- **Conducting nationwide research studies and developing tools**

Researchers use the Smart Location Database and National Walkability Index to analyze the built environment and develop models, planning tools, and databases for use by public health researchers, planners, and elected officials who make decisions about land use and transportation policies, plans, and investments. Research on walkability highlights the relationship between the perception of how walking-friendly a given area is and the quality of life, as well as how walkability potentially influences physical activity.[iii]

- **Comparing urban form among metropolitan regions**

Researchers can use these datasets in nationwide studies that compare metropolitan regions based on urban form characteristics. For instance, analysts could determine the percentage of residents that live in walkable or transit-rich neighborhoods.

- **Modeling impervious surface growth**

EPA analyzed variables in a previous version of the Smart Location Database and the National Land Cover Database [☞](http://www.mrlc.gov) <<http://www.mrlc.gov>> to create a model and simple spreadsheet tool for estimating new impervious surface growth associated with land use development scenarios. This model is sensitive not only to density of development but also to its relative centrality within the surrounding metropolitan region. For details, see EPA's Impervious Surface Growth Model <<https://epa.gov/smartgrowth/impervious-surface-growth-model>>.

[i] Block groups are contained within census tracts and generally contain between 600 and 3,000 people, with an optimum size of 1,500 people. The land area of block groups varies based on population density.

[ii] Web services are widely used by geographic information system (GIS) professionals to share geospatial data. A web service is a representation of a GIS resource (spatial data) that a server makes available to other computers or applications. Smart Location Database web services provide access to data layers through ESRI's ArcGIS Server [☞](http://www.esri.com/en/arcgis/products/arcgis-enterprise/overview) <<http://www.esri.com/en/arcgis/products/arcgis-enterprise/overview>> and Open Geospatial Consortium (OGC) [☞](http://www.opengeospatial.org/) <<http://www.opengeospatial.org/>> service formats. Web services are used to display data in the Interactive Map Viewer table of contents and are also available for public use in desktop mapping applications or web-based mapping applications.
